# Part I The Real-Time Operating System

**CHAPTER** 

ONE

# **Processes**

**Processes** are both Tasks and ISRs category 2. Trampoline category 2 ISRs are like Basic Tasks except the priority level of the interrupt controller is raised to the priority of the ISR while the later is running.

#### 1.1 The States of a Process

A process has a state used by trampoline to perform various actions on the executable when it executes a service. States include those found at page 17 and 18 of the OSEK/VDX specification ?? and 2 extra states used for internal management. The state is coded using 3 bits as shown in table 1.1.

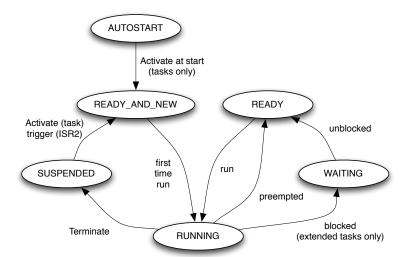

Table 1.1: States of a process

Decimal value	bit 2	bit 1	bit 0	Meaning
0	0	0	0	SUSPENDED
1	0	0	1	READY
2	0	1	0	RUNNING
3	0	1	1	WAITING
4	1	0	0	AUTOSTART
5	1	0	1	READY_AND_NEW

Figure 1.1 shows how a process goes from state to state during the lifetime of an application.

AUTOSTART This state is used to indicate what task should be started automatically when StartOS is called. An AUTOSTART task is in this initial state but no task should be in this state when the application code is running.

READY\_AND\_NEW This state is used to flag a process that is ready but has its context unitialized. This happens when the process has just been activated. The kernel initializes the context of the process the first time it goes to the RUNNING state.

**Figure 1.1:** States of a process in Trampoline. AUTOSTART is the initial state of autostart tasks. SUSPENDED is the initial state of both non autostart tasks and ISR category 2.

#### 1.2 The idle task

The "idle" task is launched when no other task is currently running. It keeps the microprocessor doing nothing.

To be able to use specific platform capabilities (to put the microcontroler in stand by mode for example), this task is hardware specific (in *machine/*). The taks is then able to quantify the microprocessor occupation.

GOIL doesn't produce anything about this idle task (unlike application(s) task(s)). The static part of the idle task descriptor is defined in 'tpl\_os\_kernel.c' and we're be able to see that:

- the priority is 0
- it's a basic task

**CHAPTER** 

# **Timing Protection Implementation**

The Timing Protection Implementation uses 2 timers. The first one is a *Free Running Timer* (FRT) which is used for *Time Frame*. The second one is a classical timer called *Timing Protection Timer* (TPT) which is used for *Execution Time Budget*, *Resource Locking Budget* and *Interrupt Disabling Budget*.

#### 2.1 Low Level Functions

These functions are provided by the *Board Support Package* and are used to manage the timers needed by the Timing Protection.

#### 2.1.1 FRT related functions

tpl\_status tpl\_start\_frt (void) starts the FRT. On a microcontroller having a FRT that starts automatically when the system is powered on, this function does nothing but must be present since it is called by Trampoline in initialization stage. An error code is returned:  $E\_OK$  means no error,  $E\_OS\_NOFUNC$  means the FRT could not be started.

tpl\_status tpl\_read\_frt(tpl\_tp\_tick \*out\_value) write the current value of the FRT in *out\_value*. An error code is returned: *E\_OK* means no error, *E\_OS\_NOFUNC* means the FRT could not be read.

tpl\_status tpl\_elapsed\_frt(tpl\_tp\_tick last\_tick, tpl\_tp\_tick \*out\_-value) write the number of ticks elapsed since <code>last\_tick</code> in <code>out\_value</code>. If the FRT has over-flown/underflown between the time <code>last\_tick</code> was get and the time <code>tpl\_elapsed\_frt</code> is called, <code>tpl\_elapsed\_frt</code> gives a correct value. An error code is returned: <code>E\_OK</code> means no error, <code>E\_OS\_NOFUNC</code> means the FRT could not be read.

#### 2.1.2 TPT related functions

tpl\_status tpl\_init\_tpt(???) initializes the TPT. An error code is returned: *E\_OK* means no error, *E\_OS\_NOFUNC* means the TPT could not be initialized.

tpl\_status tpl\_deinit\_tpt (void) deinitializes the TPT. An error code is returned:  $E\_OK$  means no error,  $E\_OS\_NOFUNC$  means the TPT could not be deinitialized.

tpl\_status tpl\_start\_tpt(tpl\_tp\_tick delay) starts the TPT with an expiration delay equal to delay ticks. At that time, the tpl\_tpt\_handler function is called. An error code is returned:  $E\_OK$  means no error,  $E\_OS\_NOFUNC$  means the TPT could not be started because it is not initialized.

tpl\_status tpl\_read\_tpt(tpl\_tp\_tick  $\star$ out\_value) write the current value of the TPT in  $out\_value$ . An error code is returned:  $E\_OK$  means no error,  $E\_OS\_NOFUNC$  means the TPT could not be read.

tpl\_status tpl\_elapsed\_tpt(tpl\_tp\_tick last\_tick, tpl\_tp\_tick  $\star$ out\_-value) write the number of ticks elapsed since  $last\_tick$  in  $out\_value$ . An error code is returned:  $E\_OK$  means no error,  $E\_OS\_NOFUNC$  means the TPT could not be read.

CHAPTER

# Schedule Table Implementation

#### Here is the files list:

- 'tpl\_as\_schedtable.c' contains the API services.
- 'tpl\_as\_st\_kernel.c' contains the kernel API services, tpl\_process\_schedtable() and tpl\_adjust\_next\_expiry\_point()
- 'tpl\_as\_action.c' contains tpl\_action\_finalize\_schedule\_table()
- 'tpl\_as\_definitions.h' contains the schedule table's states (SCHEDULETABLE\_STOPPED, SCHEDULETABLE\_BOOTSTRAP, SCHEDULETABLE\_AUTOSTART\_ABSOLUTE...)
- 'tpl\_os\_timeobj\_kernel.c' contains tpl\_remove\_time\_obj() which has been modified for the schedule table object.

The schedule table class diagram is shown in Figure 3.1 below.

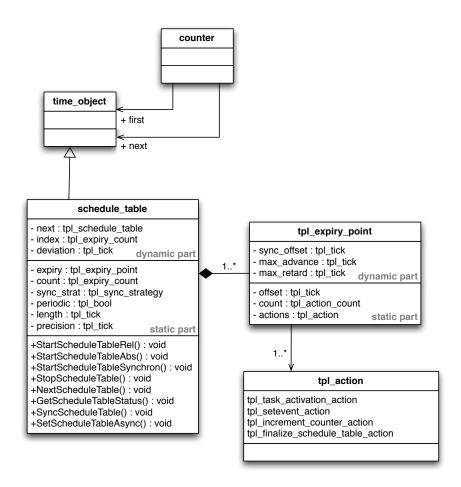

Figure 3.1: Schedule table class diagram

#### 3.1 The States of a Schedule Table

A schedule table always has a defined state. States include those found at page 42 of the AUTOSAR specifications 3.1 and others states used for internal management.

Indeed, **bit 1** is the "autostart" bit. It's used when autostarted schedule tables have been declared in the OIL file. Goil generates schedule tables with SCHEDULETABLE\_AUTOSTART\_X (X can be RELATIVE, ABSOLUTE or SYNCHRON) state. At startup (in tpl\_init\_os()), the system starts autostarted schedule tables and resets the **bit 1**.

**bit 4** is the "bootstrap" bit. It's used when the first expiry point of a schedule table is dated in more than **OsCounterMaxAllowedValue** ticks from the current date<sup>1</sup>. It can happen when:

• the schedule table start (<tick\_val>) is after the current date and the first expiry point comes be-

<sup>&</sup>lt;sup>1</sup>As the <offset> parameter of StartScheduleTableRel() cannot be greater than **OsCounterMaxAllowedValue** minus the **InitialOffset** of the schedule table (OS276), the first expiry point cannot be in more than **OsCounterMaxAllowedValue** ticks from the current date. Thus the "bootstrap" bit can set by StartScheduleTableAbs() only.

tween the current date and <tick\_val>

• <tick\_val> is before the current date and the first expiry point comes after the current date

Figure 3.2 below shows a bootstrap example for the first item.

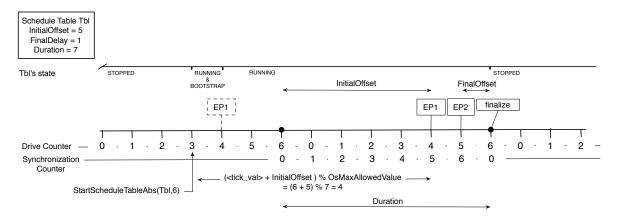

Figure 3.2: Bootstrap example

**Table 3.1:** *States of a schedule table* 

bit 5 is the "asynchronous" bit. It tells the system that the schedule table is in asynchronous mode. Thus, the different states of a schedule table are described in Table ?? below.

Decimal	bit 5	bit 4	bit 3	bit 2	bit 1	bit 0	Meaning
Value							
0	0	0	0	0	0	0	SCHEDULETABLE_STOPPED
1	0	0	0	0	0	1	SCHEDULETABLE_RUNNING
5	0	0	0	1	0	1	SCHEDULETABLE_NEXT
9	0	0	1	0	0	1	SCHEDULETABLE_WAITING
13	0	0	1	1	0	1	SCHEDULETABLE_RUNNING
							AND_SYNCHRONOUS
6	0	0	0	1	1	0	SCHEDULETABLE_AUTOSTART
							_ABSOLUTE
10	0	0	1	0	1	0	SCHEDULETABLE_AUTOSTART
							_RELATIVE
14	0	0	1	1	1	0	SCHEDULETABLE_AUTOSTART
							_SYNCHRON
16	0	1	0	0	0	0	SCHEDULETABLE_BOOTSTRAP
32	1	0	0	0	0	0	SCHEDULETABLE_ASYNC

Figure 3.3 shows how a schedule table goes from state to state.

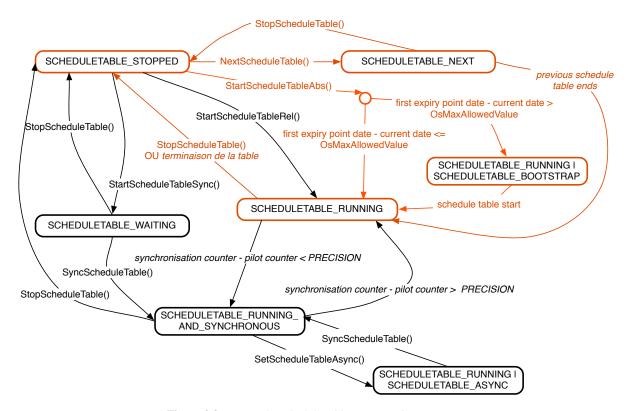

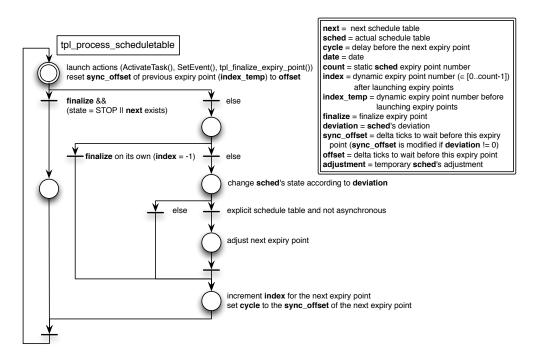

Figure 3.3: States of a schedule table in Trampoline.

## 3.2 Processing a Schedule Table

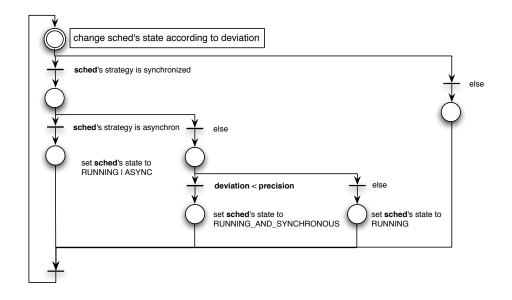

In the same time of producing the schedule tables expiry points, GOIL adds one expiry point more than the number of expiry point delared in the OIL file: the "finalize" expiry point (see Figure 3.2). Indeed, the RUNNING state of a "nexted" schedule table should be set at the finalize expiry point, thus, this expiry point has to be inserted. Moreover, for a periodic schedule table, the "finalize" expiry point helps to launch the first expiry point of the next period.

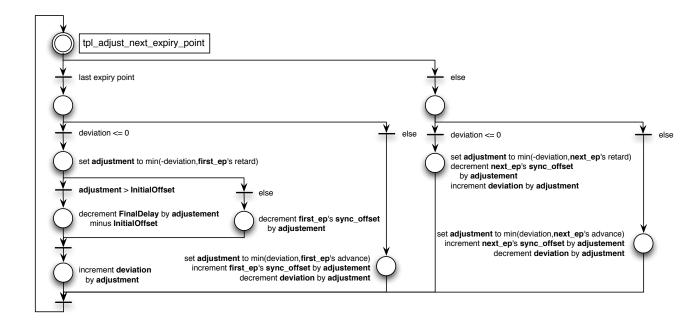

To process a **synchronized** schedule table, the schedule table's state has to be updated each expiry point and the next expiry point has to be adjusted according to the schedule table's deviation each epiry point too.

A schedule table is a time object, like an alarm. tpl\_processing\_scheduletable() is called by each expiry point (before activating a task, setting an event or finalizing a schedule table via tpl\_finalize\_expiry\_point()). The state machine of this function is shown in the Figure 3.4.

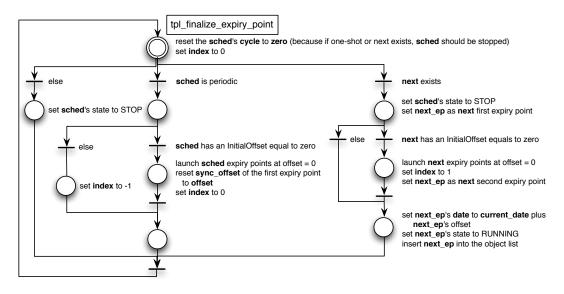

**Figure 3.4:** *tpl\_process\_scheduletable's state machine.* 

tpl\_finalize\_expoiry\_point() state machine is shown in Figure 3.5 below.

**Figure 3.5:** *tpl\_finalize\_expiry\_point's state machine.* 

CHAPTER

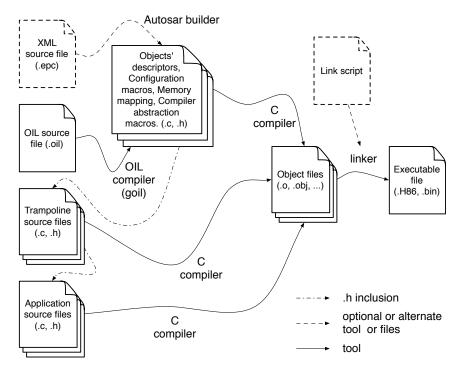

#### **FOUR**

# The communication library

## 4.1 Internals

# System generation and compilation

Trampoline is a static operating system. This means all the objects (tasks, ISR, ...) are known at compile time. This way, an application is made of tasks' code and ISRs' code, application data, and statically initialized descriptor for each object the operating system manages. A system generation tool, like goil, generates these descriptors in C files from an application configuration described in OIL or in XML. After that the Trampoline source code, the generated files and the application source code are compiled and linked together to produce an executable file as shown in figure 5.1.

**Figure 5.1:** Build process of an application with Trampoline. Starting from the left, the .c and .h corresponding to the application description given in OIL (or XML) are generated by goil (or another system generation tool, for instance an Autosar compliant one) and compiled using a C compiler. Trampoline source files are compiled too and include .h from the description for configuration purpose (see section 5.2). Application files are compiled and include .h files from Trampoline. All the object files are then linked together using an optional link script generated by goil or provided with the application.

# 5.1 The generated files

The following files are generated by goil from the OIL file or should be generated if you use a different system configuration tool. More information may be found in part ??.

File name	Usage
'tpl_app_define.h'	This file contains all the configuration macros (see section 5.2) and is included in all the Trampoline files to trigger conditional compilation. goil generates this file using the 'tplapp_define_h.goilTemplate' template file.
'tpl_app_config.h'	This file contains the declarations of the constants and functions required by the OSEK and Autosar standard (like OSMAX-ALLOWEDVALUE_x, OSTICKSPERBASE_x or OSMINCY-CLE_x constants for counter x). goil generates this file using the 'tpl_app_config_h.goilTemplate' template file.
'tpl_app_config.c'	This file contains the definitions of the constants and functions required by the OSEK and Autosar standard and the definitions of object descriptors used by Trampoline (see section ??) goil generates this file using the 'tpl_app_configc.goilTemplate' template file.
<pre>'tpl_app_custom_types.h'</pre>	Some data types used by Trampoline are not statically defined. They are generated to fit size or performance criterions. For instance, the type used for a TaskType may be a byte if there is less than 256 tasks in the system and a word otherwise. This file defined these data types.
'tpl_service_ids.h'	This file is generated only if Trampoline is compiled with service calls implemented using a system call. It contains all the identifiers of the services used by the application according to the configuration. goil generates this file using the 'tpl_service_ids_h.goilTemplate' template file.
<pre>'tpl_dispatch_table.c'</pre>	This file is generated only if Trampoline is compiled with service calls implemented using a system call. It contains the dispatch table definition. See section ??. goil generates this file using the 'tpl_dispatch_table_c.goilTemplate' template file.
'tpl_invoque.S'	This file is generated only if Trampoline is compiled with service calls implemented using a system call. It contains the API functions for system services. See section ??. The extension (here .S) may change according to the assembler used. goil generates this file using the 'tpl_invoque.goilTemplate' and 'service_call.goilTemplate' template files.
'MemMap.h'	This file is generated only if memory mapping is enabled. It contains macros for compiler abstraction memory mapping of functions and data as defined in the Autosar standard [3]. goil generates this file using the 'MemMap_h.goilTemplate' template file.

File name	Usage
'Compiler.h'	This file is generated only if memory mapping is enabled. It
	contains macros for the compiler abstraction of functions and
	pointer qualifier as defined in the Autosar standard [2]. goil gen-
	erates this file using the 'Compiler_h.goilTemplate' tem-
	plate file.
'Compiler_Cfg.h'	This file is generated only if memory mapping is enabled. It
	contains macros for the compiler abstraction configuration as
	defined in the Autosar standard [2]. goil generates this file using
	the 'Compiler_Cfg_h.goilTemplate' template file.
'script.ld'	This file is generated only if memory mapping is en-
	abled. It contains a link script to map the executable
	in the target memory. goil generates this file using the
	'script.goilTemplate' template file.

The following sections give details about the content of these files.

#### 5.2 The Configuration Macros

Trampoline can be compiled with various options. These options are controlled by setting the appropriate preprocessor configuration macros. These macros are usually set by goilusing the template found in 'tpl\_app\_define\_h.goilTemplate' file to produce the 'tpl\_app\_define.h' file that is included by the files of Trampoline. However, a different generation tool may be used and it should comply to the specification presented in the following tables. When Trampoline is compiled, the coherency and consistency of the configuration macros are checked, by using the preprocessor macros located in the 'tpl\_config\_check.h' file, to ensure they correspond to a supported configuration.

3 kinds of configuration macros are used: boolean macros, numerical macros, symbol macros and string macros. Boolean macros may take 2 values: YES or NO. All macros should be defined, Trampoline does not use the **#ifdef** or \#ifndef scheme to limit the occurrences of unwanted misconfigurations except to prevent multiple inclusions of the same header file.

#### 5.2.1 Number of objects macros

These macros gives the number of objects of each kind (tasks, ISRs, resources, ...) and other values. They are used in Trampoline to check the validity of the various identifiers and to define tables of the corresponding size:

Macro	Kind	Effect
PRIO_LEVEL_COUNT	Integer	The number of priority levels used in the system.
$TASK\_COUNT$	Integer	The number of tasks (basic and extended) used in the system.
EXTENDED_TASK_COUNT	Integer	The number of extended tasks used in the system.
ISR_COUNT	Integer	The number of ISR category 2 used in the system.

Macro	Kind	Effect
ALARM_COUNT	Integer	The number of alarms used in the system.
$RESOURCE\_COUNT$	Integer	The number of resources used in the system.
SEND_MESSAGE_COUNT	Integer	The number of send messages used in the system.
RECEIVE_MESSAGE_COUNT	Integer	The number of receive messages used in the system.
$SCHEDTABLE\_COUNT$	Integer	The number of schedule tables used in the system. This
		macros is only used when WITH_AUTOSAR is set to
		YES.
$COUNTER\_COUNT$	Integer	The number of counters used in the system. This macros
		is only used when WITH_AUTOSAR is set to YES.
$APP\_COUNT$	Integer	The number of OS applications used in the system. This
		macros is only used when WITH_AUTOSAR is set to
		YES.
$TRUSTED\_FCT\_COUNT$	Integer	The number of trusted functions used in the system. This
		macros is only used when WITH_AUTOSAR is set to
		YES.
RES_SCHEDULER_PRIORITY	Integer	The priority of the RES_SCHEDULER resource. This
		should be equal to the highest priority among the tasks.

## 5.2.2 Error Handling Macros

Error handling related macros are used to configure what kind of error Trampoline checks and what extra processing is done when an error is encountered. The following macros are available:

Macro	Kind	Effect
WITH_OS_EXTENDED	Boolean	When set to YES, Trampoline system services perform error checking on their arguments. WITH_OS_EXTENDED is set to YES with a STATUS = EXTENDED and is set to NO with a STATUS = BASIC in the oil OS object.
WITH_ERROR_HOOK	Boolean	When set to YES, the ErrorHook () function is called if an error occurs. WITH_ER-ROR_HOOK is set to YES/NO with a ER-RORHOOK = TRUE/FALSE in the oil OS object.
WITH_USEGETSERVICEID	Boolean	When set to YES, Trampoline system services store the id of the current service. This id may be retrieved in the ErrorHook() function by using the OSErrorGetServiceId() macro. WITH_USEGETSERVICEID is set to YES/NO with a USEGETSERVICEID = TRUE/FALSE in the oil OS object.

Macro	Kind	Effect
WITH_USEPARAMETERACCESS	Boolean	When set to YES, Trampoline system services store the arguments of the current service. These arguments may be retrieved in the ErrorHook () function by using the adhoc access macros (see 5.3). WITH_USEPA-RAMETERACCESS is set to YES/NO with a USEPARAMETERACCESS = TRUE/FALSE in the oil OS object.
WITH_COM_ERROR_HOOK	Boolean	When set to YES, the communication error hook is called when error occurs in the communication sub-system. This macro is only available when WITH_COM is set to true.
WITH_COM_USEGETSERVICEID	Boolean	When set to YES, Trampoline/COM system services store the id of the current service. This id may be retrieved in the COMErrorHook() function by using the COMErrorGetServiceId() macro. WITH_COM_USEGETSERVICEID is set to YES/NO with a COMUSEGETSERVICEID = TRUE/FALSE in the oil COM object.
WITH_COM_USEPARAMETERACCESS	Boolean	When set to YES, Trampoline/COM system services store the arguments of the current service. These arguments may be retrieved in the COMErrorHook() function by using the ad-hoc access macros (see ??). WITH-COM_USEPARAMETERACCESS is set to YES/NO with a COMUSEPARAMETERACCESS = TRUE/FALSE in the oil COM object.
WITH_COM_EXTENDED	Boolean	When set to YES, Trampoline/COM system services perform error checking on their arguments. WITH_COM_EXTENDED is set to YES with a COMSTATUS = EXTENDED and is set to NO with a COMSTATUS = BASIC in the oil COM object.

#### 5.2.3 Protection Macros

Protection macros deal with protection facility provided by the Autosar standard. The following Macros are available:

Macro	Kind	Effect
WITH_MEMORY_PROTECTION	Boolean	When set to YES, Trampoline enables the memory protection facility. This is only supported on some ports (MPC5510 and ARM9 at time of writing). Memory protection requires the memory mapping and the use of system call. WITH_MEMORY_PROTECTION is set to YES/NO with the MEMORY_PROTECTION attribute of MEMMAP object (see ??) set to TRUE/FALSE.
WITH_TIMING_PROTECTION	Boolean	When set to YES, Trampoline enables the timing protection facility. <i>WITH_TIMING_PROTECTION</i> is set to YES if the <i>AUTOSAR_SC</i> is 2 or 4 (see ??) and a least one of the objects specifies a timing protection related attribute in the oil file.
WITH_PROTECTION_HOOK	Boolean	When set to YES, Trampoline calls the Protection-Hook() with the appropriate argument when a protection fault occurs. <i>WITH_PROTECTION_HOOK</i> is set to YES with a <i>PROTECTIONHOOK</i> = TRUE in the oil OS object.
WITH_STACK_MONITORING	Boolean	When set to YES, Trampoline enables the stack monitoring. Each time a context switch occurs, the stack pointer is checked. If the stack pointer is outside the stack zone of the process, a fault occurs. WITHSTACK_MONITORING is set to YES with a STACK-MONITORING = TRUE in the oil OS object.

## 5.2.4 Hook call macros

Hook call macros control whether a hook is called or not. The following Macros are available:

Macro	Kind	Effect
WITH_ERROR_HOOK	Boolean	see 5.3
WITH_PRE_TASK_HOOK	Boolean	When set to YES, each time a task is scheduled, the function PreTaskHook() is called. WITH_PRE_TASKHOOK is set to YES/NO with a PRETASKHOOK = TRUE/FALSE in the oil OS object.
WITH_POST_TASK_HOOK	Boolean	When set to YES, each time a task is descheduled, the function PostTaskHook() is called. WITH-POST_TASK_HOOK is set to YES/NO with a POST-TASKHOOK = TRUE/FALSE in the oil OS object.
WITH_STARTUP_HOOK	Boolean	When set to YES, the function StartupHook() is called within the StartOS service. WITH_STARTUP_HOOK is set to YES/NO with a STARTUPHOOK = TRUE/-FALSE in the oil OS object.

Macro	Kind	Effect
WITH_SHUTDOWN_HOOK	Boolean	When set to YES, the function ShutdownHook() is
		called within the ShutdownOS service. WITH_SHUT-
		DOWN_HOOK is set to YES/NO with a SHUTDOWN-
		HOOK = TRUE/FALSE in the oil OS object.
WITH_PROTECTION_HOOK	Boolean	see 5.4

## 5.2.5 Miscellaneous macros

Here are the other available macros:

Macro	Kind	Effect
WITH_USERESSCHEDULER	Boolean	When set to YES, the RES_SCHEDULER resource is used by at least one process. WITH_USERESSCHEDULER is set to YES/NO with a USERESSCHEDULER = TRUE/FALSE in the oil OS object.
WITH_SYSTEM_CALL	Boolean	When set to YES, services are called by the mean of a system call, also known as a software interrupt (see section ??). WITH_SYS-TEM_CALL is set to YES/NO according to the target architecture and requires a memory mapping
WITH_MEMMAP	Boolean	When set to YES, a memory mapping is used: A 'MemMap.h' files giving the available memory segments is included and should be generated or provided by the user. goil generates such a file. WITH_MEMMAP is set to YES/NO with a MEMMAP = TRUE/FALSE in the oil OS object.
WITH_COMPILER_SETTINGS	Boolean	When set to YES, the compiler dependent Autosar macros are used: 'Compiler.h' and 'Compiler_Cfg.h' files are includes and should generated or provided by the user. goil generates these files if <i>MEMMAP</i> is TRUE and the <i>COMPILER</i> sub-attribute is set.
WITH_AUTOSAR	Boolean	When set to YES, Trampoline contains additional system services, code and declarations related to the Autosar standard. For instance, the counter descriptor includes the counter type (hardware or software). WITH_AUTOSAR is set to YES/NO when at least an Autosar object is present in the system configuration (oil file for instance).
TRAMPOLINE_BASE_PATH	String	The path to Trampoline root directory.

Macro	Kind	Effect
AUTOSAR_SC	Integer	The Autosar scalability class ranging from 0 to
		4. 0 means OSEK
WITH_OSAPPLICATION	Boolean	When set to YES, OS Application are used.
WITH_TRACE	Boolean	When set to YES, the tracing of the operating
		system is enabled. Only available if WITH
		TRACE is set to YES.
$TRACE\_TASK$	Boolean	When set to YES, task (de)scheduling events
		are traced. Only available if WITH_TRACE is
		set to YES.
TRACE_ISR	Boolean	When set to YES, ISR category 2
		(de)scheduling events are traced. Only
ED LOT DEG	D 1	available if WITH_TRACE is set to YES.
TRACE_RES	Boolean	When set to YES, resources get and release are
		traced. Only available if WITH_TRACE is set
TD4 CE 44 AD4	D 1	to YES.
TRACE_ALARM	Boolean	When set to YES, alarm activities are traced.
TRACE IL EVENT	D 1	Only available if WITH_TRACE is set to YES.
$TRACE\_U\_EVENT$	Boolean	When set to YES, user events are traced. Only
TRACE FORMAT	C1 1	available if WITH_TRACE is set to YES.
TRACE_FORMAT	Symbol	Trace format. A function named tpl_trace_for-
		mat_ <trace_format> is expected. Only available if WITH_TRACE is set to YES.</trace_format>
TRACE_FILE	String	File name where the trace is stored. Usable on
TRACETILE	Sumg	Posix target only. Only available if WITH
		TRACE is set to YES.
WITH IT TABLE	Boolean	When set to YES, the external interrupts are
WIIIIII	Boolean	dispatched using a table of fonction pointers.
WITH_COM	Boolean	When set to YES, internal communication is
		used.
TPL_COMTIMEBASE	Integer	The COMTIMEBASE expresses in nanosec-
		onds.
WITH_COM_STARTCOMEXTENSION	Boolean	When set to YES, the communication exten-
		sion function is called.

## 5.3 Application configuration

The application configuration is generated by goil using the template found in 'tpl\_app\_config\_-h.goilTemplate' file and 'tpl\_app\_config\_c.goilTemplate' file to produce the 'tpl\_app\_-define.h' and 'tpl\_app\_define.c' files.

#### 5.3.1 Counter related constants declaration

The 'tpl\_app\_config.h' files contains the counters related constants: those of the SystemCounter and those of the counters defined by the user. The SystemCounter constants are located in the generated files because the SystemCounter default attributes may be modified by the user in the OIL or XML file. The constants of a user defined counter are declared as follow:

```
extern CONST(tpl_tick, OS_CONST) OSTICKSPERBASE_<counter name>;
extern CONST(tpl_tick, OS_CONST) OSMAXALLOWEDVALUE_<counter name>;
extern CONST(tpl_tick, OS_CONST) OSMINCYCLE_<counter name>;
```

Where <counter name> is obviously the name given to the counter in the configuration. For the System-Counter, the following constants are declared:

```
extern CONST(tpl_tick, OS_CONST) OSTICKSPERBASE;
extern CONST(tpl_tick, OS_CONST) OSMAXALLOWEDVALUE;
extern CONST(tpl_tick, OS_CONST) OSMINCYCLE;
```

#### 5.3.2 Events definition

The 'tpl\_app\_config.c' file should contain the event mask definitions. For each event defined in the configuration, the following lines should appear:

```
#define API_START_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"

#define <event name>_mask <mask value>
CONST(EventMaskType, AUTOMATIC) <event name> = <event name>_mask;

#define API_STOP_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"
```

Where <event name> is the name given to the event in the configuration and <mask value> is the value set by the user in the configuration or, when set to AUTO, the value computed by the generation tool.

#### 5.3.3 Standard resources definition

Standard resources need the definition of an identifier used to reference the resource in a system service (GetResource() and ReleaseResource()) and an instance of a tpl\_resource structure (see ??). This is done with the following definitions:

```
#define API_START_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"

#define <resource name>_id <resource id>
CONST(ResourceType, AUTOMATIC) <resource name> = <resource name>_id;

#define API_STOP_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"
```

<sup>&</sup>lt;sup>1</sup>the default counter of an OSEK operating system

```
#define OS_START_SEC_VAR_UNSPECIFIED
#include "tpl_memmap.h"
VAR(tpl_resource, OS_VAR) <resource name>_rez_desc = {
  /* ceiling priority of the resource \star/ <resource priority>,
                                     */ O,
  /* owner previous priority
  /* owner of the resource
                                      */ INVALID_PROC_ID,
#if WITH_OSAPPLICATION == YES
 /* OS Application id
                                      */ <resource application id>,
#endif
                                      */ NULL
 /* next resource in the list
}:
#define OS_STOP_SEC_VAR_UNSPECIFIED
#include "tpl_memmap.h"
```

Where <resource name> is the name given to the resource in the configuration, <resource priority> is the priority of the resource that is computed by the generation tool and is the maximum priority of the processes that use the resource and <resource application id> is the identifier of the OS Application the resource belongs to. Since this field is protected by WITH\_OSAPPLICATION, it may be leaved empty when no OS Application is used.

<resource id> ranges from 0 to the number of standard resources minus 1. Once every standard resource descriptor is defined, a table gathering pointers to the resource descriptors and indexed by the resource id has to be defined. This table is used by system services to get the resource descriptor from the resource id. Suppose 3 standard resource, *motor1*, *motor2* and *dac* has been defined and RES\_SCHEDULER is used, the table should be as follow:

```
#define OS_START_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"
CONSTP2VAR(tpl_resource, AUTOMATIC, OS_APPL_DATA)
tpl_resource_table[RESOURCE_COUNT] = {
    &motor1_rez_desc,
    &motor2_rez_desc,
    &dac_rez_desc,
    &res_sched_rez_desc
};
#define OS_STOP_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"
```

&res\_sched\_rez\_desc, the pointer to the resource descriptor of RES\_SCHEDULER should always be the last element of the table. If RES\_SCHEDULER is not used, simply remove it from the table.

#### 5.3.4 Tasks definition

Each task needs an identifier to reference a task un a system service (ActivateTask(), ChainTask(), GetTaskState(), SetEvent() and GetEvent()) and the declaration of the task function. The following definitions should appear for each task:

```
#define API_START_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"
```

```
#define <task name>_id <task id>
CONST(TaskType, AUTOMATIC) <task name> = <task name>_id;
#define API_STOP_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"

#define APP_Task_<task name>_START_SEC_CODE
#include "tpl_memmap.h"

FUNC(void, OS_APPL_CODE) <task name>_function(void);
#define APP_Task_<task name>_STOP_SEC_CODE
#include "tpl_memmap.h"
```

Where <task name> is the name given to the task in the configuration and <task id> is the identifier of the task computed by the system generation tool. Task ids should range from 0 to the number of tasks minus 1. In addition, id allocation must start with extended tasks first and basic task after. In addition an instance of the static task descriptor must be provided:

```
#define OS_START_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"
CONST(tpl_proc_static, OS_CONST) <task name>_task_stat_desc = {
                           */ <task name>_CONTEXT,
 /* context
 /* stack
                            */ <task name>_STACK,
 /* entry point (function) */ <task name>_function,
/* internal resource */ <internal resource>,
  /* task id
                             */ <task name>_id,
#if WITH_OSAPPLICATION == YES
                            */ <application>,
 /* OS application id
#endif
 */ <task type>
 /* task type
#if WITH_AUTOSAR_TIMING_PROTECTION == YES
 /* pointer to the timing
                           \star/ ,<timing protection>
    protection descriptor
#endif
};
#define OS_STOP_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"
```

Where <task name> is the name given to the task in the configuration. <internal resource> mays be one of the following:

- a pointer to the internal resource descriptor (see ??) if an internal resource has been defined in the configuration;
- a pointer to the scheduler internal resource if the task has been defined as non-preemptable in the configuration;
- NULL if none of the above cases apply.

<application> is the id of the OS Application the task belongs to when OS Application are used or, when they are not used, nothing at all. <task priority> is the priority of the task as computed by the system generation tool. <task activation> is the maximum number of task activation allowed as defined in the configuration. <task type> may be EXTENDED or BASIC. <timing protection> is a pointer to the timing protection descriptor or NULL if no timing protection is defined for the task.

Also an instance of the dynamic task descriptor must be provided:

```
#define OS_START_SEC_VAR_UNSPECIFIED
#include "tpl_memmap.h"
VAR(tpl_proc, OS_VAR) <task name>_task_desc = {
                                  */ NULL,
 /* resources
#if WITH_MEMORY_PROTECTION == YES
 /* if > 0 the process is trusted */ <trusted count>,
#endif /* WITH_MEMORY_PROTECTION */
                                    */ O,
 /* activate count
                                    */ <task priority>,
 /* task priority
  /* task state
                                   */ <task state>
#if WITH_AUTOSAR_TIMING_PROTECTION == YES
  /* activation allowed
                                  */ ,TRUE
#endif
};
#define OS_STOP_SEC_VAR_UNSPECIFIED
#include "tpl_memmap.h"
```

Where <task name> is the name given to the task in the configuration. <trusted count> is 0 if the task belongs to a non trusted OS Application and 1 if the tasks belongs to a trusted OS Application. <task priority> is the priority of the task as computed by the system generation tool. <task state> is the initial state of the task and must be set to AUTOSTART or SUSPENDED.

If the task is an EXTENDED one, an event mask descriptor is added:

```
VAR(tpl_task_events, OS_VAR) <task name>_task_evts = {
   /* event set */ 0,
   /* event wait */ 0
};
```

Where <task name> is the name given to the task in the configuration.

# Ports details

#### 6.1 PowerPC

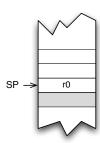

#### 6.1.1 System services

The PowerPC port uses the sc software interrupt to call system services [1]. sc stands for System Call. It saves the current *PC* in *SRR0* register and the current *MSR* in *SRR1* register and jump to the System Call handler.

The id of the system service to call is given in the r0 register and r0 save and restore are added around. For instance, the following listing gives the ActivateTask service code. These function are generated from templates by goil (see 5.1) and are part of the *invoque* layer (see ??):

```
.global ActivateTask
ActivateTask:
 subi r1, r1, 4
                                    /* make room on stack
 stw r0,0(r1)
                                    /* save r0
      r0,OSServiceId_ActivateTask
 li
                                    /* load r0 with the id
                                    /* system call
 lwz r0,0(r1)
                                    /* restore r0
 addi r1,r1,4
                                    /* restore stack
                                    /* return
 blr
  .type ActivateTask,@function
  .size ActivateTask, $$-ActivateTask
```

When the System Call begin execution, the process stack has the mapping depicted in figure 6.1.

**Figure 6.1:** Process stack mapping at the beginning of the System Call handler. The grayed zone represents an unknown content depending on from where the service was called

#### 6.1.2 Dispatching the service call

The System Call handler is usually located in the  $0C00_H$  exception handler but, depending on the CPU kind, it may be located elsewhere. Since the available memory for the interrupt or exception handler may vary, a jump is made to the tpl\_sc\_handler.

tpl\_sc\_handler performs the following tasks:

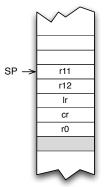

- 1. saves additional registers to be able to work
- 2. disables memory protection
- 3. switches to kernel stack if needed
- 4. calls the service
- 5. performs a context switch if needed and programs the MPU.
- 6. switches back to the process stack if needed
- 7. enable memory protection
- 8. restore registers
- 9. get back to the process

Note: Currently the PowerPC port does not support tasks that use floating point registers

#### Saving additional registers

The following registers are saved: lr, cr, r11 and r12. In fact, it should be not necessary to save r11 and r12 because these registers are volatile as defined in the PowerPC EABI [4] but we prefer a conservative approach. Register saving is done by the following code at start of the tpl\_sc\_handler and the mapping of the process stack is depicted at figure 6.2:

```
subi
     r1,r1,PS_FOOTPRINT /* Make room on stack */
stw
      r11, PS_R11(r1)
                           /* Save r11
stw
      r12, PS_R12(r1)
                          /* Save r12
mflr
     r11
stw
      r11, PS_LR(r1)
                           /* Save lr
mfcr r11
                          /* Save cr
     r11, PS_CR(r1)
stw
```

**Figure 6.2:** Process stack mapping after additional registers have been saved by the beginning of the System Call handler.

#### Disabling memory protection

This part of the dispatch layer is done in the  $tpl\_enter\_kernel$  function and is assembled only if  $WITH\_MEMORY\_PROTECTION$  is set to YES. After saving the lr, the  $tpl\_kernel\_mp$  function is called and does the actual job. At last lr is restored.

#### Switching to the kernel stack

Once the dispatch layer has saved the registers it uses and has switched to the kernel memory protection scheme, it switches to the kernel stack. However the kernel stack could used already because a call to a PreTaskHook or a PostTaskHook is done on the kernel stack and such a hook may call a service. So the dispatch layer is reentrant. The number of reentrant calls is counted by the *tpl\_reentrancy\_counter*. In addition the process stack pointer (*r1*), *SRR0* and *SRR1* are saved in the kernel stack. The kernel stack mapping is shown in figure 6.3. For a reentrant call, the same frame is build over the current one. The switch to the kernel stack is done as follow:

```
* Check the reentrency counter value and increment it
 \star if the value is 0 before the inc, then we switch to
 * the system stack.
*/
lis
     r11, TPL_HIG (tpl_reentrancy_counter)
     r11, r11, TPL_LOW(tpl_reentrancy_counter)
ori
                   /* get the value of the counter */
lwz
     r12,0(r11)
cmpwi r12,0
addi r12, r12, 1
stw
     r12,0(r11)
bne
     no_stack_change
/*
 * Switch to the kernel stack
 * Get the pointer to the bottom of the stack
*/
    r11, TPL_HIG (tpl_kernel_stack_bottom)
lis
ori r11,r11,TPL_LOW(tpl_kernel_stack_bottom)
stw r1,KS_SP-KS_FOOTPRINT(r11) /* save the sp of the caller */
                                  /* set the kernel stack */
     r1, r11
mr
```

6.1. PowerPC 29

```
no_stack_change:
   /*
   * make space on the stack to call C functions
   */
subi r1,r1,KS_FOOTPRINT
```

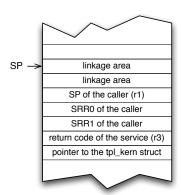

Figure 6.3: Kernel stack mapping after allocation.

#### Calling the service

Since the registers used to pass parameters to a function, that is r3 to r10 as documented in [4], have not been changed until now, calling the function that implements the service respects the register usage conventions.

The first thing to do is to get the function pointer corresponding to the service id. The service id is in r0 as explained in 6.1.1 and is used as an index to the  $tpl\_dispatch\_table$ .

The second thing to do is to reset the *tpl\_need\_switch* flag that triggers a context switch. This flag (a byte) is located in the *tpl\_kern* kernel struct. This is done as follow:

```
lis r11,TPL_HIG(tpl_kern)
ori r11,r11,TPL_LOW(tpl_kern)
stw r11,KS_KERN_PTR(r1) /* save the ptr for future use */
li r0,NO_NEED_SWITCH
stb r0,20(r11)
```

In the future *tpl\_kern* will be reused, so its address is saved in the kernel stack.

Then, to allow reentrancy for a service call in a hook, the *RI* bit of the *MSR* is set to 1. Without that, a sc cannot be properly executed.

```
mfmsr r11
ori r11,r11,RI_BIT_1
mtmsr r11
```

At last, the service is called:

blrl

#### Context switch

The *tpl\_need\_switch* flag that as been possibly modified by the service is now checked to do a context switch if needed.

```
lwz r11,KS_KERN_PTR(r1) /* get back the tpl_kern address */
lbz r12,20(r11) /* get the tpl_need_switch flag */
andi. r0,r12,NEED_SWITCH /* check if a switch is needed */
beg no_context_switch
```

A context switch is performed in 3 steps. The first one is the context save of the process that loses the CPU. This step is optional because if the service was a TerminateTask or a ChainTask, the context needs not to be saved. This information is in the *tpl\_need\_switch* flag. Before doing the actual context save, the return value of the service must be saved in the proper location of the kernel stack. The tpl\_save\_context function will read it from this location and expects a pointer to the context saving area or the process in *r3*. *s\_old*, the address of the context saving area, is in another member of *tpl\_kern*. At the end, the *tpl\_kern* address is reread because *r11* has been destroyed in tpl\_save\_context.

```
stw r3,KS_RETURN_CODE(r1) /* save the return value */
andi. r0,r12,NEED_SAVE /* r12 contains tpl_need_switch */
beq no_save
lwz r3,0(r11) /* r11 contains the tpl_kern address */
bl tpl_save_context /* and s_old is put into r3 */
lwz r11,KS_KERN_PTR(r1) /* get back tpl_kern address */
```

The second step consists in loading the configuration of memory protection for the process that get the CPU by calling the tpl\_set\_process\_mp function. This function expects the id of the process in r3. Again this id is located in member proc\_id of tpl\_kern. This is done only if WITH\_MEMORY\_-PROTECTION is YES.

```
#if WITH_MEMORY_PROTECTION == YES
  lwz r3,16(r11) /* get the id of the process which get the cpu */
  bl tpl_set_process_mp /* set the memory protection scheme */
#endif
```

The third step loads the context of the process that get the CPU. The address of *tpl\_kern* is loaded into *r11* because it has been destroyed in tpl\_set\_process\_mp, *s\_running*, the address of the context saving area of the current process is loaded into *r3* and tpl\_load\_context is called. At last, *r3* is restored.

6.1. PowerPC 31

#### Switching back to the process stack

At this stage, the *SRR0* and *SRR1* registers saved in the kernel stack are restored. The space reserved in the kernel stack is freed. The reentrancy counter is decremented and the stack switches to the process stack if the reentrancy counter is 0.

```
r11,KS_SRR0(r1)
mtspr spr_SRR0,r11
lwz r11, KS_SRR1(r1)
mtspr spr_SRR1,r11
addi r1, r1, KS_FOOTPRINT
                              /* free back space on the stack */
 * The reentrency counter is decremented. If it reaches
 * 0, the process stack is restored
lis
    r11, TPL_HIG (tpl_reentrancy_counter)
ori r11,r11,TPL_LOW(tpl_reentrancy_counter)
    r12,0(r11)
                 /* get the value of the counter */
lwz
subi r12, r12, 1
    r12,0(r11)
stw
cmpwi r12,0
    no_stack_restore
bne
/* Restore the execution context of the caller
   (or the context of the task/isr which just got the CPU)
     r1, KS_SP-KS_FOOTPRINT(r1) /* Restore the SP and switch
                                     back to the process stack */
```

#### Enabling memory protection

Then, if memory protection is used, the user scheme is reenabled. The actual works depends on the kind of MPU and is done in tpl\_user\_mp.

#### Restoring registers

Registers saved at stage 1 on the process stack are restored an the stack is freed.

```
lwz r11,PS_CR(r1)
mtcr r11
```

```
lwz r11,PS_LR(r1)
mtlr r11
lwz r12,PS_R12(r1)
lwz r11,PS_R11(r1)
addi r1,r1,PS_FOOTPRINT
```

#### Getting back to the process

At last, the dispatch layer is exited using a rfi.

```
rfi /* return from interrupt */
```

#### 6.1.3 Interrupt handler

#### 6.1.4 The CallTrustedFunction service

The CallTrustedFunction service is implemented by the tpl\_call\_trusted\_function\_-service function. This function is a special case of service because the kernel stack and the process stack have to be modified. In addition, an <code>ExitTrustedFunction</code> service is implemented to restore the process stack when the trusted function exits. Both services have to be written in assembly language since C does not allow to explicitly modify the stack.

tpl\_call\_trusted\_function\_service performs the following steps:

- 1. check the trusted function id is within the allowed range
- 2. increment the trusted counter of the calling process
- 3. build a frame on the process stack to store the registers pushed by a service call except for r0 and for SRR0 and SRR1; put the address of <code>ExitTrustedFunction</code> in the lr location in the process stack; save SRR0 and SRR1 in the process stack
- 4. get the trusted function address and put it in SRR0
- 5. go back to the dispatch layer

#### Checking the trusted function id

The id of the trusted function is checked to avoid to call a function at an arbitrary address.

#### Incrementing the trusted counter

The trusted counter of the process is incremented each time a trusted function is called. When the trusted counter is > 0, the process is trusted. In such a case, the dispatch layer does not enable memory protection when scheduling the process so it has an unlimited access to the whole addressing space.

6.1. PowerPC 33

#### Building the frame

The frame is used to store the calling context of the trusted function and is shown in figure 6.4. The following code builds this frame:

```
* First get back the process stack pointer
lwz r11, KS_SP(r1)
 * Make room to prepare the call of the trusted function
subi r11, r11, PS_TRUSTED_FOOTPRINT_IN
 * store ExitTrustedFunction as the return address
     r12, TPL_HIG (ExitTrustedFunction)
ori
     r12, r12, TPL_LOW (ExitTrustedFunction)
stw
    r12,PS_LR(r11)
* Update the stack pointer
*/
stw
     r11, KS_SP (r1)
* second get back SRRO and SRR1 and save them to the process stack
*/
    r12,KS_SRR0(r1)
stw
    r12,PS_SRR0_IN(r11)
    r12,KS_SRR1_IN(r1)
lwz
    r12,PS_SRR1(r11)
stw
```

#### Setting the trusted function address

34

The *SRR0* saved by the dispatch layer after the CallTrustedFunction is changed to the address of the trusted function. This way, instead of returning to the caller, the trusted function will be executed.

```
lis r11,TPL_HIG(tpl_trusted_fct_table)
ori r11,r11,TPL_LOW(tpl_trusted_fct_table)
slwi r0,r3,2
lwzx r12,r11,r0
stw r12,KS_SRRO(r1)
```

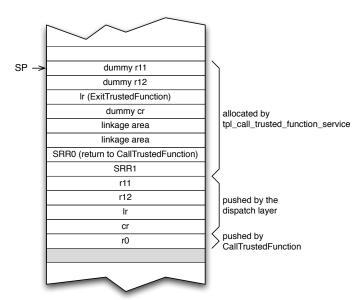

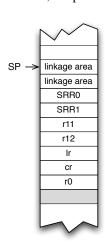

Figure 6.4: Process stack mapping at the end of tpl\_call\_trusted\_function\_service. r0, at the bottom of the stack has been pushed by CallTrustedFunction. cr to r11 has been pushed by the dispatch layer. SRR0 and SRR1 are saved here by tpl\_call\_trusted\_function\_service to be able to go back to the calling process. Above, the linkage area allows the trusted function to call functions. Above, a frame that will be used by the dispatch layer to restore an execution context for the trusted function is built.

#### Going back to the dispatch layer

A simple blr goes back to the dispatch layer. The latter cleans up the process stack. Once the trusted function starts execution, the process stack is like that:

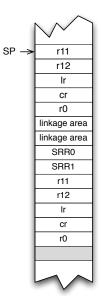

**Figure 6.5:** Process stack mapping when the trusted function starts its execution.

#### 6.1.5 The ExitTrustedFunction service

When a trusted function finishes, the context of the CallTrustedFunction must be restored to return to the caller. ExitTrustedFunction should not be called explicitly because its address has been set as the return address of the trusted function by tpl\_call\_trusted\_function\_service. Calling ExitTrustedFunction explicitly would result in an undefined behavior or in the crash of the calling process but see below. The mapping of the process stack at start of tpl\_exit\_trusted\_function\_service is shown in figure 6.6.

6.1. PowerPC 35

**Figure 6.6:** Process stack mapping when the tpl\_exit\_-trusted\_function\_service function starts its execution.

First, tpl\_exit\_trusted\_function\_service decrements the trusted counter of the calling process. A particular attention must be given to this point because by building a fake stack frame and calling Explicitly ExitTrustedFunction to underflow this counter, a process could get a full access to the memory. So the counter is tested before to avoid to go under 0.

```
/* get the ptr to tpl_kern */
      r11,KS_KERN_PTR(r1)
1 w z.
lwz
      r11,12(r11)
                            /* get the ptr to the runnning process desc */
      r12,4(r11)
                            /* get trusted_count member */
lwz
 * Warning, the trusted counter has to be check (compared to 0) to
 * avoid to decrement it if it is already 0. Without that a process
 \star could build an had-hoc stack an call explicitly ExitTrustedFunction
 * to get access to all the memory.
 */
cmpwi r12,0
                            /* check it is not already at 0 */
                            /* uh uh */
beq
    cracker_in_action
subi r12,r12,1
                            /* decrement it */
     r12,4(r11)
                            /* put it back in the process desc */
stw
```

tpl\_exit\_trusted\_function\_service has to remove from the process stack the frame that was built by tpl\_call\_trusted\_function\_service, restore *SRRO* and *SRR1* before returning to the dispatch layer.

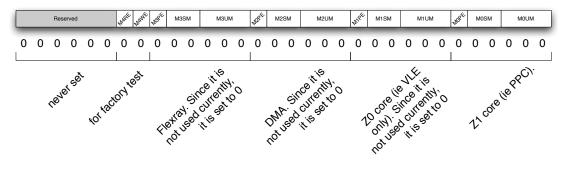

```
cracker_in_action:
   /*
   * get the process stack pointer
   */
lwz r11,KS_SP(r1)
   /*
   * get back the SRRO and SRR1
```

```
*/
lwz
      r12, PS_SRR0_OUT(r11)
stw
      r12,KS_SRR0(r1)
      r12, PS_SRR1_OUT(r11)
1 w z
      r12, KS_SRR1 (r1)
stw
 * free the process stack and update it in the kernel stack

#### 6.1.6 The MPC5510 Memory Protection Unit

The access control rights of the memory region descriptor rules the access of 5 bus masters (labeled from 4 to 0). Unused bus masters are set to the same access right for all the regions. Bus master 4 is used for factory testing only, so the access rights should be set to no access. Bus master 3 is the Flexray controller. Since it is not used in the current version of Trampoline, it is set to no access to. Bus master 2 is the DMA controller. For the same reason it is set to no access. Bus master 1 is the Z0 core. Again it is set to no access.

The access control rights register has the following bit usage:

Bus master 4 is a special case. The 2 bits have the following meaning:

Bit	Meaning
M4RE	If set to 1, bus master 4 may <b>read</b> memory in the region. If 0, no read is allowed
M4WE	If set to 1, bus master 4 may write memory in the region. If 0, no write is allowed

So in our case, these bits are set to 0.

6.1. PowerPC 37

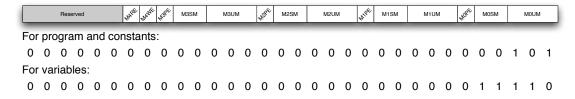

Of course, other bus masters have more sophisticated access right:

Bit	Meaning
MxPE	The PID Enable bit. Set to 0 in our case
MxSM	These 2 bits rules the supervisor mode access control with the following meaning: $00 =$
	rwx, $01 = rx$ , $10 = rw$ , $11 = same$ as defined by MxUM. In our case, it is set to $00$
	for code and constants and to 11 for data.
MxUM	These 2 bits rules the user mode access control. The first bit means $r$ , the second one $w$
	and the third one $x$ .

#### Trampoline uses 4 descriptors:

Descriptor	Usage	MxUM value
MPU_RGD0	Constants and program <sup>1</sup> .	rwx = 00 for supervisor mode, $rx = 101$
		for user mode.
MPU_RGD1	Private variables of the process.	rw = 110 for supervisor and user mode.
MPU_RGD2	Stack of the process.	rw = 110 for supervisor and user mode.
MPU_RGD3	Variables of the OS Application if	rw = 110 for supervisor and user mode.
	OS Applications are used.	

#### So values of access control bits should be:

#### So in hexa:

Kind	Value
Program region access	0x00000005
Variable region access	0x0000001E

<sup>&</sup>lt;sup>1</sup>This region is set to the whole addressing space. This is not definitive and should be improved because reading a peripheral control register should be protected. So an additional descriptor has to be used to allow the kernel (supervisor mode) a complete access on all the memory space and no access at all for applications (user mode).

#### What happen in case of memory protection violation?

Two exception handler are used to handle a memory protection violation, one for data access, one for code access.

The Data Storage exception is tied to the IVOR 2 vector (VPR offset = 0x020), see page 8-2 of the MPC5510 Microcontroller Family Reference Manual.

The Instruction Storage exception is tied to the IVOR 3 vector (VPR offset = 0x030), see page 8-2 of the MPC5510 Microcontroller Family Reference Manual.

However, it appears one of these exceptions is raised when the processor is in user mode. The behavior is different in supervisor mode *to be completed*.

6.1. PowerPC 39

# Part II The Goil system generator

# The Goil templates

Goil includes a template interpreter which is used for file generation. Goil generates the structures needed by trampoline to compile the application and may generate other files like a memory mapping file 'MemMap.h', the compiler abstraction files, 'Compiler.h' and 'Compiler\_cfg.h' and a linker script depending on which attributes you set in the OIL file.

A template is a file which is located in the default template directory (set with the environment variable GOIL\_TEMPLATES or with the **--templates** option on the command line) or in the directory of your project. Goil starts by looking for a template in the directory of your project, then, if the template is not found, in the default templates directory.

Four sets of templates are used:

- code generation templates that are located in the 'code' subdirectory of the template directory;
- build system templates that are located in the 'build' subdirectory;
- compiler dependent stuff in the 'compiler' subdirectory and
- linker script templates in the 'linker' subdirectory.

Templates are written using a simple language which allow to access the application configuration data and to mix them with text to produce files.

Files are produced by a template program located in the 'root.goilTemplate' file which is as the root of the template directory. By default the following files are produced:

- 'tpl\_app\_config.c' by using the 'tpl\_app\_config.c.goilTemplate' file
- 'tpl\_app\_config.h' by using the 'tpl\_app\_config.h.goilTemplate' file
- 'Makefile' (if option -g or --generate-makefile is given) by using the 'Makefile.goilTemplate' file
- 'script.ld' (if memory mapping is used and if the default name is not changed) by using the 'script.goilTemplate' file
- 'MemMap.h' (if memory mapping is used) by using the 'MemMap.h.goilTemplate' file
- $\bullet$  'Compiler.h' (if memory mapping is used) by using the 'Compiler.h.goilTemplate' file
- 'Compiler\_Cfg.h' (if memory mapping is used) by using the 'Compiler\_Cfg.h.goilTemplate' file

# 7.1 The configuration data

The configuration data are computed by Goil from the OIL source files, from the options on the command line and from the 'target.cfg' file. They are available as a set of predefined boolean, string, integer or list variables. All these variables are in capital letters.

**Warning:** Some configuration data are not listed here because they are dependent on the target. For instance, the STACKSIZE data may be an attribute of each item of a *TASKS* list for ppc target but are missing for the c166 target.

#### 7.1.1 The PROCESSES, TASKS, BASICTASKS, EXTENDEDTASKS, ISRS1 and ISRS2 lists

Theses variables are lists where informations about the processes used in the application are stores:

List	Content
PROCESSES	the list of processes. The items are sorted in the following order: ex-
	tended tasks, then basic tasks, then ISRs category 2.
TASKS	the list of tasks, basic and extended. The items are sorted in the following
	order: extended tasks, then basic tasks.
BASICTASKS	the list of basic tasks.
<b>EXTENDEDTASKS</b>	the list of extended tasks.
ISRS1	the list of ISR category 1.
ISRS2	the list of ISR category 2.

Each item of these lists has the following attributes:

Item	Type	Content
NAME	string	the name of the process.
PROCESSKIND	string	the kind of process: "Task" or "ISR".
EXTENDEDTASK	boolean	true if the process is an extended task, false otherwise.
NONPREEMPTABLE	boolean	true if the process is a non-preemptable task, false oth-
		erwise.
PRIORITY	integer	the priority of the process.
ACTIVATION	integer	the number of activation of a task. 1 for and extended
		task or an ISR.
AUTOSTART	boolean	true if the process is an autostart task, false otherwise.
USEINTERNALRESOURCE	boolean	true if the process is a task that uses an internal re-
		source, false otherwise.
INTERNALRESOURCE	string	the name of the internal resource if the process is a task
		that uses an internal resource, empty string otherwise.
RESOURCES	list	The resources used by the process. Each item has the
		following attribute: NAME

<sup>&</sup>lt;sup>1</sup>In Trampoline, a process is a task or an ISR category 2.

#### 7.1.2 The COUNTERS, HARDWARECOUNTERS and SOFTWARECOUNTERS lists

This list contains all the informations about the counters used in the application, including the *System-Counter*.

List	Content
COUNTERS	the list of counters, both hardware and software as long as the Sys-
	temCounter
<b>HARDWARECOUNTERS</b>	the list of hardware counters including the SystemCounter.
SOFTWARECOUNTERS	the list of software counters.

Each item of this list has the following attributes:

Item	Type	Content
NAME	string	the name of the counter.
TYPE	string	the type of counter: "HARDWARE_COUNTER" or
		"SOFTWARE_COUNTER".
MAXALLOWEDVALUE	integer	the maximum allowed value of the counter.
MINCYCLE	integer	the minimum cycle value of the counter.
TICKPERBASE	integer	the number of ticks needed to increment the counter.
SOURCE	string	the interrupt source name of the counter. This can be
		used to wrap interrupt vector to a counter incrementa-
		tion function

#### 7.1.3 The EVENTS list

This list contains the informations about the events of the application. Each item has the following attributes:

Item	Type	Content
NAME	string	the name of the event.
MASK	integer	the mask of the event.

## 7.1.4 The ALARMS list

This list contains the informations about the alarms of the application. Each item has the following attributes:

Item	Type	Content	
NAME	string	the name of the alarm.	
COUNTER	string	the name of the counter that drives the alarm.	
ACTION	string	the action to be done when the alarm expire. It can take the following values: "setEvent", "activateTask" and "callback". The last action is not available in Autosar mode.	
TASK	string	the name of the task on which the action is performed. This attribute is defined for "setEvent" and "activate-Task" actions only.	
EVENT	string	the name of the event to set on the target task. This attribute is defined for "setEvent" action only.	
AUTOSTART	boolean	true if the alarm is autostart, false otherwise	
ALARMTIME	integer	the alarm time of the alarm. This attribute is set if AUTOSTART is true	
CYCLETIME	integer	the cycle time of the alarm. This attribute is set if AUTOSTART is true	
APPMODE	string	the application mode in which the alarm is autostart. This attribute is set if AUTOSTART is true	

# 7.1.5 The REGULARRESOURCES and INTERNALRESOURCES lists

These lists contains the informations about the resources of the application.

List	Content
REGULARRESOURCES	the list of STANDARD and LINKED resources.
INTERNALRESOURCES	the list of INTERNAL resources.

Each item has the following attributes:

Item	Type	Content
NAME	string	the name of the resource.
PRIORITY	integer	the priority of the resource.
TASKUSAGE	list	the list of tasks that use the resource. Each item of this list has an attribute NAME which is the name of the task.

Item	Type	Content
ISRUSAGE	list	the list of ISRs that use the resource. Each item of
		this list has an attribute NAME which is the name of the
		ISR.

# 7.1.6 The MESSAGES, SENDMESSAGES and RECEIVEMESSAGES lists

These lists contain the informations about the messages of the application.

List	Content
MESSAGES	the list of messages, both send and receive message.
SENDMESSAGES	the list of send messages.
RECEIVEMESSAGES	the list of receive messages.

#### Each item has the following attributes

Item	Type	Content		
NAME	string	the name of the message.		
MESSAGEPROPERTY	string	the type of the message. It can be "RECEIVE_ZERO_INTERNAL", "RECEIVE_UNQUEUED_INTERNAL", "RECEIVE_QUEUED_INTERNAL", "SEND_STATIC_INTERNAL", "SEND_ZERO_INTERNAL" or "RECEIVE_ZERO_SENDERS".		
NEXT	string	the name of the next message in a receive message chain. This attribute is defined for receive messages only.		
SOURCE	string	the name of the send message which is connected to the receive message. This attribute is defined for re- ceive messages only.		
CTYPE	string	the C language type of the message. This attribute is not defined for "RECEIVE_ZERO_INTERNAL" and "SEND_ZERO_INTERNAL" messages.		
INITIALVALUE	string	initial value of the receive message. This attribute is defined for "RECEIVE_UNQUEUED_INTERNAL" and "RECEIVE_ZERO_SENDERS" messages only.		
QUEUESIZE	integer	queue size of a receive queued message. This attribute is defined for "RECEIVE_QUEUED_INTERNAL" messages only.		
TARGET	string	target message of a send message. This is the first message in a receive message chain. This attribute is defined for "SEND_STATIC_INTERNAL" and "SEND_ZERO_INTERNAL" messages only.		

Item	Type	Content
FILTER	string	the kind of filter to apply. This attribute may take the following values: "ALWAYS", "NEVER", "MASKEDNEWEQUALSX", "MASKEDNEWISEQUAL", "NEWISDIFFERENT", "MASKEDNEWEQUALSMASKEDOLD", "MASKEDNEWDIFFERSMASKEDOLD", "NEWISWITHIN", "NEWISOUTSIDE", "NEWISGREATER", "NEWISLESSOREQUAL", "NEWISLESS", "NEWISGREATEROREQUAL" or "ONEEVERYN".
MASK	integer	Mask of the filter when needed. This attribute is defined for "MASKEDNEWEQUALSX", "MASKEDNEWDIFFERSX", "MASKEDNEWE-QUALSMASKEDOLD" and "MASKEDNEWDIFFERSMASKEDOLD" filters only.
Х	integer	Value of the filter when needed. This attribute is defined for "MASKEDNEWEQUALSMASKEDOLD" and "MASKEDNEWDIFFERSX" filters only.
MIN	integer	Minimum value of the filter when needed. This attribute is defined for "NEWISWITHIN" and "NEWISOUTSIDE" filters only.
MAX	integer	Maximum value of the filter when needed. This attribute is defined for "NEWISWITHIN" and "NEWISOUTSIDE"
PERIOD	integer	Period of the filter. This attribute is defined for "ONEEVERYN" filter only.
OFFSET	integer	Offset of the filter. This attribute is defined for "ONEEVERYN" filter only.
ACTION	string	the action (or notification) to be done when the message is delivered. It can take the following values: "setEvent" or "activateTask".
TASK	string	the name of the task on which the notification is performed. This attribute is defined for "setEvent" and "activateTask" actions only.
EVENT	string	the name of the event to set on the target task. This attribute is defined for "setEvent" notification only.

# 7.1.7 The SCHEDULETABLES list

This list contains the informations about the schedule tables of the application.

Item	Type	Content
NAME	string	the name of the schedule table.
COUNTER	string	the name of the counter which drives the schedule table.

Item	Type	Content			
PERIODIC	boolean	true if the schedule table is a periodic one, false other-			
		wise.			
SYNCSTRATEGY	string	the synchronization strategy of the schedule table. This attribute may take the following values: "SCHEDTABLE_NO_SYNC", "SCHEDTABLE_IMPLICIT_SYNC" or "SCHEDTABLE_EXPLICIT_SYNC".			
PRECISION	integer	the precision of the synchronization. This attribute is define when SYNCSTRATEGY is "SCHEDTABLE EX-			
		PLICIT_SYNC".			
STATE	string	the state of the schedule table. This attribute may take the following values: "SCHEDULETABLE_STOPPED",			
		"SCHEDULETABLE_AUTOSTART_SYNCHRON",			
		"SCHEDULETABLE_AUTOSTART_RELATIVE" or			
		"SCHEDULETABLE_AUTOSTART_ABSOLUTE".			
DATE	integer	the start date of the schedule table. This attribute has an actuel value when STATE is "SCHEDULETABLE			
		AUTOSTART_RELATIVE" or "SCHEDULETABLE_AU-			
		TOSTART_ABSOLUTE", otherwise it is set to 0.			
LENGTH	integer	The length of the schedule table.			
EXPIRYPOINTS	list	The expiry points of the schedule table. See the following table for items attributes.			

Each item of the  ${\tt EXPIRYPOINTS}$  list has the following attributes:

Item	Type	Content
ABSOLUTEOFFSET	integer	the absolute offset of the expiry points.
RELATIVEOFFSET	integer	the relative offset of the expiry points from the previ-
		ous expiry point.
MAXRETARD	integer	maximum retard to keep the schedule table syn-
		chronous.
MAXADVANCE	integer	maximum advance to keep the schedule table syn-
		chronous.
ACTIONS	list	the actions to perform on the expiry point. See the
		following table for items attributes.

Each item of the  ${\tt ACTIONS}$  list has the following attributes:

Item	Type	Content
ACTION	string	the action to be done when the alarm expire. It can
		take the following values: "setEvent", "activateTask",
		"incrementCounter" and "finalizeScheduleTable".

Item	Type	Content
TASK	string	the name of the task on which the action is performed.
		This attribute is defined for "setEvent" and "activate-
		Task" actions only.
EVENT	string the name of the event to set on the target task	
		attribute is defined for "setEvent" action only.
TARGETCOUNTER	string	the name of the counter to increment. This attribute is
		defined for "incrementCounter" action only.

# 7.1.8 The OSAPPLICATIONS list

This list contains the informations about the OS Applications of the application.

Item	Type	Content
NAME	string	the name of the OS Application.
RESTART	string	the name of the restart task. This attribute is not defined is there is no restart task for the
		OS Application.
PROCESSACCESSVECTOR	string	access right for the processes
PROCESSACCESSITEMS	string	access right for the processes as bytes in a table
PROCESSACCESSNUM	integer	number of elements in the previous table
ALARMACCESSVECTOR	string	access right for the alarms
ALARMACCESSITEMS	string	access right for the alarms as bytes in a table
ALARMACCESSNUM	integer	number of elements in the previous table
RESOURCEACCESSVECTOR	string	access right for the resources
RESOURCEACCESSITEMS	string	access right for the resources as bytes in a table
RESOURCEACCESSNUM	integer	number of elements in the previous table
SCHEDULETABLEACCESSVECTOR	string	access right for the schedule tables
SCHEDULETABLEACCESSITEMS	string	access right for the schedule tables as bytes in a table
SCHEDULETABLEACCESSNUM	integer	number of elements in the previous table
COUNTERACCESSVECTOR	string	access right for the software counters
COUNTERACCESSITEMS	string	access right for the software counters as bytes in a table
COUNTERACCESSNUM	integer	number of elements in the previous table
PROCESSES	list	list of the processes that belong to the OS Application. Each item has an attribute NAME which is the name of the process.
HASSTARTUPHOOK	boolean	true if the OS Application has a startup hook.
HASSHUTDOWNHOOK	boolean	true if the OS Application has a shutdown hook.
TASKS	list	list of the tasks that belong to the OS Application. Each item has an attribute NAME which is the name of the task.

Item	Type	Content
ISRS	list	list of the ISRs that belong to the OS Application. Each item has an attribute NAME which is the name of the ISR.
ALARMS	list	list of the alarms that belong to the OS Application. Each item has an attribute NAME which is the name of the alarm.
RESOURCES	list	list of the resources that belong to the OS Application. Each item has an attribute NAME which is the name of the resource.
REGULARRESOURCES	list	list of the standard or linked resources that belong to the OS Application. Each item has an attribute NAME which is the name of the resource.
INTERNALRESOURCES	list	list of the internal resources that belong to the OS Application. Each item has an attribute NAME which is the name of the resource.
SCHEDULETABLES	list	list of the schedule tables that belong to the OS Application. Each item has an attribute NAME which is the name of the schedule table.
COUNTERS	list	list of the counters that belong to the OS Application. Each item has an attribute NAME which is the name of the counter.
MESSAGES	list	list of the messages that belong to the OS Application. Each item has an attribute NAME which is the name of the messages.

#### 7.1.9 The TRUSTEDFUNCTIONS list

This list contains the informations about the trusted functions of the application. Each item contains one attribute only.

Item	Type	Content
NAME	string	the name of the trusted function.

#### 7.1.10 The READLIST list

This list contains the informations about the ready list. Items are sorted by priority from 0 to the maximum computed priority. The only attribute of each item is the size of the queue.

Item	Type	Content
SIZE	integer	the size of the queue for the corresponding priority.

# 7.1.11 The SOURCEFILES, CFLAGS, CPPFLAGS, ASFLAGS, LDFLAGS and TRAMPOLINE-SOURCEFILES lists

The SOURCEFILES list contains the source files as found in attributes APP\_SRC of the OS object in the OIL file.

Item	Type	Content
FILE	string	the source file name.

The *CFLAGS* list contains the flags for the C compiler as found in attributes CFLAGS of the OS object in the OIL file.

Item	Type	Content
CFLAG	string	the C compiler flag.

The  $\it CPPFLAGS$  list contains the flags for the C++ compiler as found in attributes CPPFLAGS of the OS object in the OIL file.

Item	Type	Content
CPPFLAG	string	the C++ compiler flag.

The ASFLAGS list contains the flags for the assembler as found in attributes ASFLAGS of the OS object in the OIL file.

Item	Type	Content
ASFLAG	string	the assembler flag.

The LDFLAGS list contains the flags for the linker as found in attributes LDFLAGS of the OS object in the OIL file.

Item	Type	Content
LDFLAG	string	the linker flag.

The TRAMPOLINESOURCEFILES list contains the trampoline source files used by the application.

Item	Type	Content
DIRECTORY	string	the directory of the source file relative to the Trampo-
		line root directory ('os', 'com' or 'autosar').
FILE	string	the source file name.

#### 7.1.12 The INTERRUPTSOURCES list

This list is extracted from the 'target.cfg' file. Each item has the following attribute:

Item	Type	Content
NAME	string	the name of the interrupt source. This is one of the
		name used in the OIL file as value for the SOURCE
		attribute
NUMBER	string	the id of the interrupt source.

#### 7.1.13 Scalar data

The following scalar data are defined:

Data	Type	Content
APPNAME	string	name of executable as given in the APP_NAME attribute in the OS object
ARCH	string	name of the architecture. This is the first item in the target.
ASSEMBLEREXE	string	name of the assembler executable used. This is the ASSEMBLER attribute in the OS object. It is set to <i>as</i> by default. It is used for build dependent templates.

Data	Type	Content
ASSEMBLER	string	name of the assembler used. This is the ASSEMBLER
		attribute in the MEMMAP attribute of the OS object. It
		is used for assembler dependent templates.
AUTOSAR	boolean	true if Trampoline is compiled with the Autosar exten-
		sion.
BOARD	string	name of the board. This is the third item (if any) in the
		target.
CHIP	string	name of the chip. This is the second item (if any) in
		the target.
COMPILEREXE	string	name of the compiler executable used. This is the
		COMPILER attribute in the OS object. It is set to gcc
		by default. It is used for build dependent templates.
		Do not confuse with the COMPILER data.
COMPILER	string	name of the compiler used. This is the COMPILER
		attribute in the MEMMAP attribute of the OS object. It
		is used for compiler dependent templates.
CPUNAME	string	name given to the OIL CPU object
EXTENDED	boolean	true if Trampoline is compiled in extended error han-
		dling mode.
FILENAME	string	the name of the file which will be written as the result
		of the computation of the current template.
FILEPATH	string	the full absolute path of the file which will be written
		as the result of the computation of the current template.
NATIVEFILEPATH	string	the full absolute path of the file which will be written
		as the result of the computation of the current template
		in native OS format.
ITSOURCESLENGTH	integer	number of interrupt sources as defined in the
		'target.cfg' file.
LINKEREXE	string	name of the linker executable used. This is the
		LINKER attribute in the OS object. It is set to gcc by
		default. It is used for build dependent templates. Do
		not confuse with the LINKER data.
LINKER	string	name of the linker used. This is the LINKER attribute
		in the MEMMAP attribute of the OS object. It is used for
		linker dependent templates.
LINKSCRIPT	string	name of the link script file as given in the MEMMAP
		attribute of the OS object.
MAXTASKPRIORITY	integer	the highest computed priority among the tasks.
OILFILENAME	string	name of the root OIL source file
PROJECT	string	name of the project. The name of the project is the <b>-p</b>
		(or <b>project</b> ) value if it is set or the name of the oil
		file without the extension.
SCALABILITYCLASS	integer	the Autosar scalability class used by the application. If
		Autosar is not enabled, SCALABILITYCLASS is set
		to 0.
TARGET	string	name of the target. This is the <b>-t</b> (or <b>target</b> ) option
		value of goil.

Data	Type	Content
TEMPLATEPATH	string	path to the template root directory. This is the
		templates option value of goil or the value of the
		GOIL_TEMPLATES environment variable.
TIMESTAMP	string	current date
TRAMPOLINEPATH	string	path to the trampoline root directory. This is the
		TRAMPOLINE_BASE_PATH attribute of the OS ob-
		ject. It defaults to "".
USECOMPILERSETTINGS	boolean	true if memory mapping is enabled (Goil generates
		the 'Compiler.h' and 'Compiler_Cfg.h' files and
		Trampoline includes them).
USEBUILDFILE	boolean	true if a build file is used for the project ie option <b>-g</b> or
		generate-makefile is given.
USECOM	boolean	true if the application uses OSEK COM.
USEERRORHOOK	boolean	true if Trampoline uses the Error Hook.
USEGETSERVICEID	boolean	true if Trampoline uses the service ids access macros.
USEINTERRUPTTABLE	boolean	true if the wrapping of interrupt vector to glue func-
		tions used to increment a counter or to activate an ISR2
		(for instance) should be generated. The actual code
		generation is up to the port.
USELOGFILE	boolean	true if goil generates a log file, ie option -l orlogfile
		is given.
USEMEMORYMAPPING	boolean	true if memory mapping is enabled (Goil generates the
		'MemMap.h' file and Trampoline includes it).
USEMEMORYPROTECTION	boolean	true if Trampoline uses the Memory Protection.
USEOSAPPLICATION	boolean	true if Trampoline uses OS Applications.
USEPARAMETERACCESS	boolean	true if Trampoline uses the parmaters access macros.
USEPOSTTASKHOOK	boolean	true if Trampoline uses the Post-Task Hook.
USEPRETASKHOOK	boolean	true if Trampoline uses the Pre-Task Hook.
USEPROTECTIONHOOK	boolean	true if Trampoline uses the Protection Hook.
USERESSCHEDULER	boolean	true if Trampoline uses the RES_SCHEDULER re-
		source.
USESHUTDOWNHOOK	boolean	true if Trampoline uses the Shutdown Hook.
USESTACKMONITORING	boolean	true if Trampoline uses the Stack Monitoring.
USESTARTUPHOOK	boolean	true if Trampoline uses the Startup Hook.
USESYSTEMCALL	boolean	true if services are called using a System Call (i.e. a
		software interrupt).
USETIMINGPROTECTION	boolean	true if Trampoline uses Timing Protection.
USETRACE	boolean	true if tracing is enabled.

# 7.2 The Goil template language (or GTL)

A template is a text file with file extension '.goilTemplate'. This kind of file mixes literal text with an embedded program. Some instructions (see section 7.5.6) in the embedded program outputs text as a result of the program execution and this text is put in place of the instructions. The resulting file is then

stored.

The template interpreter starts in literal text mode. Switching from literal text mode to program mode and back to text mode is done when a '%' is encountered. A literal '%' and a literal '\' may be used by escaping them with a '\'.

# 7.3 GTL types

GTL supports 4 types: **string**, **integer**, **boolean** and **list**. These types have readers to get informations about a variable. A reader is invoke with the following syntax:

[expression reader]

#### 7.3.1 string readers

The following readers are available for string variables:

Item	Type	Meaning
HTMLRepresentation	string	this reader returns a representation of the string suitable for an HTML encoded representation. '&' is encoded by & amp; , '"' by " , '<' by < and '>' by > .
identifierRepresentation	string	this reader returns an unique representation of the string conforming to a C identifier. Any Unicode character that is not a latin letter is transformed into its hexadecimal code point value, enclosed by '_' characters. This representation is unique: two different strings are transformed into different C identifiers. For example: value3 is transformed to value_33_; += is transformed to _2B3D; An_Identifier is transformed to An_5F_Identifier.
lowercaseString	string	this reader returns lowercased representation of the string.
length	integer	this reader returns the number of characters in the string
stringByCapitalizingFirstCharacter	string	if the string is empty, this reader returns the empty string; otherwise, it returns the string, the first character being replaced with the corresponding upper case charac- ter.
uppercaseString	string	this reader returns uppercased representa- tion of the receiver

#### 7.3.2 boolean readers

The following readers are available for boolean variables:

Item	Type	Meaning
trueOrFalse	string	this reader returns "true" or "false" accord-
		ing to the boolean value
yesOrNo	string	this reader returns "yes" or "no" according
		to the boolean value
unsigned	integer	this reader returns 0 or 1 according to the
		boolean value

#### 7.3.3 integer readers

The following readers are available for integer variables:

Item	Type	Meaning
string	string	This reader returns the integer value as a
		character string.
hexString	string	this reader returns an hexadecimal string representation of the integer value.

#### 7.3.4 list readers

The following reader is available for list variables:

Item	Type	Meaning
length	integer	this reader returns the number of objects
		currently in the list.

# 7.4 GTL operators

## 7.4.1 Unary operators

C	perator	<b>Operand Type</b>	Result Typ	e   Meaning
	+	integer	integer	no operation.
	$\sim$	integer	integer	bitwise not.
	not	boolean	boolean	boolean not.
	exists	any variable	boolean	true if the variable is defined, false other-
				wise. But see below

#### A second form of **exists** is:

```
exists var default (expression)
```

*var* and *expression* should have the same type. If *var* exists, the returned value is the content of *var*. If it does not exist, *expression* is returned.

#### 7.4.2 Binary operators

Operator	<b>Operands Type</b>	Result Type	Meaning
+	integer	integer	add.
-	integer	integer	substract.
*	integer	integer	multiply.
/	integer	integer	divide.
&	integer	integer	Bitwise and.
&	boolean	boolean	boolean and.
	integer	integer	Bitwise or.
	boolean	boolean	boolean or.
$\wedge$	integer	integer	Bitwise xor.
$\wedge$	boolean	boolean	boolean xor.
	string	string	string concatenation.
<<	integer	integer	shift left.
>>	integer	integer	shift right.
!=	any	boolean	comparison (different).
==	any	boolean	comparison (equal).
<	integer or boolean	boolean	comparison (lower than).
<=	integer or boolean	boolean	comparison (lower or equal).
>	integer or boolean	boolean	comparison (greater).
>=	integer or boolean	boolean	comparison (greater or equal).

# 7.4.3 Constants

Constant	Type	Meaning
emptyList	list	this constant is an empty list
true	boolean	true boolean

Constant	Type	Meaning
false	boolean	false boolean
yes	boolean	true boolean
no	boolean	false boolean

#### 7.5 GTL instructions

#### 7.5.1 The *let* instruction

Data assignment instruction. The general form is:

```
let var := expression
```

A second form allows to add a string to a list (only, this should be extended in the future)

```
let var += expression
```

var is a list and expression is a string.

The scope of a variable depends on the location where the variable is assigned the first time. For instance, in the following code:

```
let a := 1
foreach TASKS do
  let b := INDEX
  let a := INDEX
end foreach
!a !b
```

Because a is assigned outside the **foreach** loop, it contains the value of the last INDEX after the **foreach**. Because b is assigned inside the **foreach** loop, it does not exist after the loop anymore and **!b** will trigger and error.

#### 7.5.2 The *if* instruction

Conditional execution. The forms are:

```
if expression then ... end if
if expression then ... else ... end if
if expression then ... elsif expression then ... end if
if expression then ... elsif expression then ... else ... end if
```

The *expression* must be boolean. In the following example, the blue text (within the %) is produced only if the USECOM boolean variable is true:

```
if USECOM then %
#include "tpl_com.h" %
end if
```

7.5. GTL instructions 59

#### 7.5.3 The *foreach* instruction

This instruction iterates on the elements of a list. Each element may have many attributes that are available as variables within the **do** section of the foreach loop. The simplest form is the following one

```
foreach expression do ... end foreach
```

In the following example, for each element in the ALARMS list, the text between the **do** and the **end foreach** is produced with the NAME attribute of the current element of the ALARMS list inserted at the specified location. INDEX is not an attribute of the current element. It is generated for each element and ranges from 0 to the number of elements in the list minus 1.

```
foreach ALARMS do
%
/* Alarm % !NAME % identifier */
#define % !NAME %_id % !INDEX %
CONST(AlarmType, AUTOMATIC) % !NAME % = % !NAME %_id;
%
end foreach
```

A more general form of the foreach instruction is:

```
foreach expression prefixedby string
  before ...
  do ...
  between ...
  after ...
end foreach
```

**prefixedby** is optional and allows to prefix the attribute names by *string*. If the list is not empty, the **before** section are executed once before the first execution of the **do** section. The **between** section is executed between the execution of the **do** section. If the list is not empty, the **after** section is executed once after the last execution of the **do** section.

In the following example, a table of pointers to alarm descriptors is generated:

#### 7.5.4 The for instruction

The **for** instruction iterates along a literal list of elements.

```
for var in expression, ..., expression do
```

```
end for
```

At each iteration, *var* gets the value of the current *expression*. As in the **foreach** instruction, INDEX is generated and ranges from 0 to the number of elements in the list minus 1.

#### 7.5.5 The loop instruction

The **loop** instruction is the classical integer loop. Its simplest form is:

```
loop var from expression to expression do
    ...
end loop
```

Like in the foreach instruction, before, between and after sections may be used:

```
loop var from expression to expression
before ...
do ...
between ...
after ...
end loop
```

#### 7.5.6 The ! instruction

! emits an expression. The form is:

```
! expression
```

#### 7.5.7 The ? instruction

? stores in a variable a number of spaces equal to the current column in the output. The form is:

```
? var
```

#### 7.5.8 The *template* instruction

The **template** instruction includes the output of another template in the output of the current template. Its simplest form is the following one:

```
template template_file_name
```

If the file *template file\_name*.goilTemplate does not exist, an error occurs. To include the output of a template without generating an error, use the following form:

61

```
template if exists template_file_name
```

A third form allows to execute instructions when the included template file is not found:

7.5. GTL instructions

```
template if exists template_file_name or ... end template
```

At last, it is possible to search templates in a hierarchy (code, linker, compiler, build) different from the current one. For instance to include a template located in the linker hierarchy, use one of the following forms:

```
template template_file_name in hierarchy
template if exists template_file_name in hierarchy
template if exists template_file_name in hierarchy or ... end template
```

In all cases, the included template inherits from the current variables table but works on its own local copy.

#### 7.5.9 The write instruction

The write instruction defines a block where the template processing output is captured to be written to a file. The general form is:

```
write to expression :
    ...
end write
```

Where expression is a string expression.

In the following example, the result of the 'script' template is written to the link script file.

```
if exists LINKER then
  write to PROJECT."/".LINKSCRIPT:
    template script in linker
  end write
end if
```

#### 7.5.10 The *error* and *warning* instructions

It can be useful to generate an error or a warning if a data is not defined or if it looks strange. For instance if a target needs a STACKSIZE for a task or if the STACKSIZE is too large for a 16bit target. **error** and **warning** have 2 forms:

```
error var expression
warning var expression
and
error here expression
warning here expression
```

expression must be of type string. In the first form, var is a configuration data. The file location of this configuration may be a location in the OIL file or in the template file if the variable was assigned in the template. In the second form, **here** means the current location in the template file.

In the following example an error is generated for each task with not STACKSIZE attribute in the OIL file:

```
foreach TASKS do
   if not exists STACKSIZE then
    error NAME "STACKSIZE of Task " . NAME . " is not defined"
   end if
end foreach
```

In this second example, an error is generated if a template is not found:

```
template if exists interrupt_wrapping or
   error here "interrupt_wrapping.goilTemplate not found"
end template
```

#### 7.6 Examples

Here are examples of code generation using GTL.

#### 7.6.1 Computing the list of process ids

```
foreach PROCESSES do
   if PROCESSKIND == "Task" then
%
/* Task % !NAME % identifier */
#define % !NAME %_id % !INDEX %
CONST(TaskType, AUTOMATIC) % !NAME % = % !NAME %_id;
%
   else
%
/* ISR % !NAME % identifier */
#define % !NAME %_id % !INDEX
    if AUTOSAR then
    #
     # ISR ids constants are only available for AUTOSAR
    #
%
CONST(ISRType, AUTOMATIC) % !NAME % = % !NAME %_id;
%
   end if
end if
end foreach
```

#### 7.6.2 Computing an interrupt table

```
if USEINTERRUPTTABLE then
  loop ENTRY from 0 to ITSOURCESLENGTH - 1
  before

# define OS_START_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"

CONST(tpl_it_vector_entry, OS_CONST)
tpl_it_table[% !ITSOURCESLENGTH %] = {
```

7.6. Examples 63

```
do
      let entryFound := false
      foreach INTERRUPTSOURCES prefixedby interrupt_ do
        if ENTRY == interrupt_NUMBER then
          # check first for counters
          foreach HARDWARECOUNTERS prefixedby counter_ do
            if counter_SOURCE == interrupt_NAME & not entryFound then
              % { tpl_tick_% !interrupt_NAME %, (void *)NULL }%
              let entryFound := true
            end if
          end foreach
          if not entryFound then
            foreach ISRS2 prefixedby isr2_ do
              if isr2_SOURCE == interrupt_NAME & not entryFound then
                % { tpl_central_interrupt_handler_2, (void*)%
                !([TASKS length] + INDEX) % }%
                let entryFound := true
              end if
            end foreach
          end if
        end if
      end foreach
      if not entryFound then
       % { tpl_null_it, (void *)NULL }%
      end if
   between %,
    after
};
#define OS_STOP_SEC_CONST_UNSPECIFIED
#include "tpl_memmap.h"
 end loop
end if
7.6.3 Generation of all the files
This is the default 'root.goilTemplate' file
write to PROJECT."/tpl_app_config.c":
  template tpl_app_config_c in code
end write
write to PROJECT."/tpl_app_config.h":
  template tpl_app_config_h in code
end write
write to PROJECT."/tpl_app_define.h":
  template tpl_app_define_h in code
end write
if exists COMPILER then
```

응

```
write to PROJECT."/MemMap.h":
    template MemMap_h in compiler
end write
write to PROJECT."/Compiler.h":
    template Compiler_h in compiler
end write
write to PROJECT."/Compiler_Cfg.h":
    template Compiler_Cfg_h in compiler
end write
end if

if exists LINKER then
    write to PROJECT."/".LINKSCRIPT:
    template script in linker
end write
end if
```
